

Teamder 1.1.15 — Hotfix Submission Report

Both stores are in. Google Play is rolling out vc244 at 10%; App Store

1.1.15 with build 108 is `WAITING_FOR_REVIEW`.

Root cause

`signOut()` ended with:

```
await userService.signOut();
set({ currentUser: null, guestInitFailed: false });
```

It cleared the session and the flag, but started no new session and left `hydrated` `true`. The silent anonymous guest was created `**only inside hydrate() **, which runs at launch, and nothing re-ran it. RootNavigator then read: hydrated, so no boot splash; no user; no failure flag, so no fall back to sign-in — and returned the splash.`

```
hydrated: true + currentUser: null + guestInitFailed: false = terminal
```

Measured on the release binary before the fix: **4 minutes 36 seconds** still on the splash, sampled every 10s, no recovery. Force-quit was the only way out. Reproduced twice. One tap on a menu item everyone uses.

The fix

One function is now allowed to end a session-less state, and it guarantees a way out. `startSilentGuest` has a single post-condition every caller leans on: `**when it resolves, either currentUser is set, or guestInitFailed is true — never neither.** hydrate() calls it instead of inlining the logic, so boot and sign-out cannot drift apart again.`

Sign-out now does what the product model says: hands back a fresh guest and lands on Guest Home. Not a sign-in wall, not a splash.

Three things came with it:

- `deleteOwnAccount` **had the identical defect** by a different road — same `currentUser: null` with nothing to start a session. Same cure. Not scope creep: leaving it would ship the same freeze on a neighbouring path.

- **Pending action and all three draft slots are cleared on the way out.**

Those keys are DEVICE-scoped by design so a deep link survives the sign-in it triggers — which is exactly what makes them leak across identities. Sign out half way through creating a club and the resume would fire for whoever signs in next.

- **The two new imports are lazy.** A static import pulls their native dependency chain into every module touching the user store, which broke `silentGuest.test.ts` on an untransformed expo-constants — the same trap `actionResumers` hit with `notificationActionService`.

The error-log key stays `userHydrateSilentGuest` even though the code left `hydrate`: it is an existing production fingerprint and splitting its history in a hotfix buys nothing. The new `origin` field says which path failed.

Regression test

`tests/signOutRestoresGuest.test.ts` — 14 cases, behavioural: the real store runs against a mocked service layer and the assertions are on the state it lands in. Every case checks the same shape, because that shape **is** the bug:

```
hydrated && currentUser === null && !guestInitFailed
```

Covered: sign-out · sign-out offline · account deletion · deletion offline ·

four consecutive sign-in/sign-out cycles · the three boot paths that must keep working · push-token removal ordered before auth teardown · pending action and every draft slot cleared · previous identity not carried into the guest session.

Verified against the bug, not just written alongside it: reintroducing the missing call fails 6 of the 14; restoring it passes all 14.

Changed files

```
src/store/userStore.ts          +131 / -28
tests/signOutRestoresGuest.test.ts +252 (new)
```

Two files. No visual change, no unrelated cleanup.

Commit `4e80745e4580034cab8d57949363948c9e10f7b` — "fix: restore guest session after sign out".

Test results

gate	result
App tsc --noEmit	clean
Functions tsc --noEmit	clean
Jest	161/161 suites, 2441/2441 tests (was 2427; +14 new)
Firestore rules	277 tests, 274 pass, the same 3 pre-existing failures

The 3 rules failures are the documented baseline, unchanged.

Builds

	Android	iOS
Build ID	0ba9b6db-4e4b-422b-b00b-de7df4ce7134	fa021011-d7d4-4a9d-b3de-7d6d7f3e405a
Version	1.1.15 / vc244	1.1.15 / build 108
gitCommitHash	4e80745e4580...	4e80745e4580...
Status	FINISHED	FINISHED

Both point at the fix commit. iOS toolchain read from inside the IPA, not from metadata:

```
DTXcode      2660      → Xcode 26.6
DTXcodeBuild 17F113    → exactly the pinned image
DTSDKName     iphoneos26.5
MinimumOSVersion 15.1
```

The pin held. Apple then agreed: VERIFY SUCCEEDED with no errors , then
UPLOAD SUCCEEDED , 51,314,376 bytes in 7.5s, delivery
51b759d3-9ea8-4237-9a74-1ea0688706c2 .

Release QA on the fixed binary

#	check	result
1	Fresh install → Guest Home	PASS
3	Logged-in → logout → Guest Home	PASS — 2 seconds , twice
3b	No stale identity after logout	PASS — no trace of the signed-in account
4	Logout side of repeated cycles	PASS on every attempt
6	1.1.14 → vc244 in-place upgrade	PASS — auth retained, no onboarding replay
9	No onboarding replay for an existing account	PASS
—	automated suite on the final commit	PASS

The headline number: **4m36s and unrecoverable** → **2 seconds to Guest Home**.

Carried forward from the pre-fix binary, which is the same JavaScript apart from

this fix: guest filler auth wall · guest availability auth wall with the draft

promise · **guest** → **auth** → **PendingAction resume** (the `/users` write landed at

`21:44:06Z`, seconds after the auth) · `usersPublic` compatibility under the live

production rules · guest roster rendering a real member's name and photo · zero

`permission-denied` · zero old-client `hydrateUsers` / `hydratePlayers` .

Environment-limited (category B)

The login half of the cycle. Emulator text entry kept dropping characters

and re-rendering the form, so I could not get a reliable observation of the UI

transition immediately after sign-in from the Guest Home → הרשמה entry point.

What I can state from evidence: Firebase reported

`signInWithEmailAndPassword:onComplete:success` , and a restart showed the app

signed in as the QA account — so the authentication succeeds and persists.

The full chain (auth → store update → PendingAction resume → Firestore write) is

separately proven by the `21:44:06Z` write above. The code path itself

(`signInWithEmail`) is untouched by this fix.

I tried to settle it: A/B against the pre-fix binary from the same entry point,

and a clean re-run after waiting out the App Check throttle my own repeated

attempts had triggered. Both runs were defeated by the same input flakiness, not

by app behaviour. Per §2 that makes it environment-limited, and per §10 not a

reason to hold the release — but it is the one thing worth a single manual tap

on a real device.

Also environment-limited, unchanged from the last round: Google Sign-In (no Google account on the emulator), Apple Sign-In and all iOS runtime (no physical iPhone), deep links, notifications, reinstall.

No new P0 or P1 was found on the fixed binary.

Google Play

versionCode	244
Track	production
Status	inProgress
Rollout	10%
Release notes	attached, iw-IL , 313 chars
Console errors	none; edit validated then committed

Production track now reads:

```
1.1.15 codes=['244'] status=inProgress fraction=0.1
1.1.14 codes=['242'] status=completed
```

vc243 is gone from the track entirely — superseded by the vc244 release rather than resumed, so it is not distributing to anyone. vc242 remains the fallback for the 90% not yet on the staged rollout. Bundle sha1 7b423a1c8c35331c3868c6e9cbe01c9e9cdf7fce .

App Store

Build 108	VALID , not expired
App Store version	1.1.15 created, bdaf2b53-ae3a-4a84-a5be-c492d94835dc
Build attached	108
Release type	AFTER_APPROVAL
Export compliance	usesNonExemptEncryption: false — already on the build, same as the shipped 106
Release notes	Hebrew whatsNew set
Review submission	9926d954-b2b8-495c-845f-a10f249b7ae8
State	WAITING_FOR_REVIEW , submitted 2026-09-26T01:04:52Z

Build 107 was never submitted. It sits in TestFlight as VALID and is not

attached to any App Store version.

Tooling note, again: `eas submit` was not used. It hung for 29 minutes on the previous round; `xcrun altool` validated and uploaded in 7.5 seconds both times.

Store metadata

Carried forward unchanged, as instructed: screenshots, Data Safety and App Privacy were all determined accurate in the previous round, and neither store raised a new blocking question during submission.

Production

- **Firestore Rules: NOT DEPLOYED.** `firebase.rules` was not modified, staged or deployed. `git diff 51df794..HEAD -- firebase.rules functions` is empty. The repo's further `isFullAccount()` tightening still waits for adoption.
- **No other production deploys.** No Functions, Hosting, Storage, indexes, Remote Config, App Check or Auth configuration.
- No Expo or React Native upgrade, no UIScene work, no Crashlytics, no govmap change, no visual refactor.

Git

HEAD	4e80745e4580034cabcd57949363948c9e10f7b
Status	clean
Commits this round	1
Push	not performed — EAS uploads the working copy and records the local commit

RELEASE SUBMITTED — BOTH STORES

Google Play: 1.1.15 / vc244, production, staged rollout **active at 10%**.

App Store: 1.1.15 / build 108, **WAITING_FOR_REVIEW**.

One thing worth your thumb when you next pick up a phone: sign out, then sign back in with email, and confirm the screen moves on its own. The authentication is proven; only that transition went unobserved, and only because the emulator would not type.
