

Joryio SDK update + move to the production host

Teamder · 28.09.2026 · e92331b · source: HippoCampus-Tech/Hippomation@5ad4b99

1 · The version number is not a signal

Our snapshot and upstream **both** read `1.2.0` — and **27 files differed**. Everything done upstream since our 07.09 snapshot shipped without a version bump.

Compare trees, not numbers. "Same version" is not a reason to skip a pull.

2 · What the pull brought

Four init options	<code>anonymousId</code> , <code>sendImmediately</code> , <code>maxQueueSize</code> , <code>requestTimeout</code> — the bridge dropped these on the floor : a JS app that set any of them got the native default and no error
<code>enableInAppMessages</code>	now exposed on the class
<code>submitInAppForm</code>	forms inside messages, with a new request model
minSdk	the bridge declared 24 and silently raised every consumer; corrected to the 23 the native SDK actually declares

The app uses none of these yet, so no application code changed on our side.

3 · Two local patches survived

The five companion forwarders — fifth pull in a row

The React Native module calls `optOut`, `optIn`, `isUserOptedOut`, `syncInAppCampaigns` and `resetDisplayedCampaigns` **statically**, and upstream still declares all five as instance methods only. Without the patch, `:joryio_react-native-sdk:compileReleaseKotlin` fails with `Unresolved reference`.

Why it keeps coming back: the parity tripwire greps the SDK sources for method **names**, and a grep cannot tell an instance method from a static one. So it keeps approving a bridge that does not compile.

This time I did not trust a grep either — I **parsed the companion object**: of the 17 names the bridge calls on the `Joryio` type, it carries 12. The same five are missing.

`joryio-ui` cannot be published at all

It declares `sdkVersion = "1.0.0"` beside a base publishing `1.2.0`, and its `pom.withXml` appends a **second element** to a POM that already has one. That is invalid, and Gradle refuses the publication outright — so the artifact could not be released.

4 · The iOS bridge is clean, but one asymmetry remains

All 37 symbols the bridge calls on `Joryio.shared` exist.

⚠️ `IdentifyRequest` on iOS still carries only `userId` + `attributes`, where Android's also carries `anonymousId`. So `alias()` remains the only call that stitches an anonymous device to a user on both platforms — unchanged from our earlier note.

5 · Hosts — everything on production

What	Was	Now
<code>verify_joryio.sh</code>	<code>hippomation-backend.fly.dev</code> — the retired test backend	<code>api-eu1.joryio.com</code>
6 Python tools	<code>JORYIO_BASE_URL</code> defaulting to <code>""</code>	<code>api-eu1.joryio.com</code>
The app itself	already correct	unchanged

Both defaults failed quietly. A "verification" run that passed against a decommissioned host proved nothing about the host the app talks to, and an unset environment variable sent requests to a bare path — a failure that reads like an API fault.

Verification — by building, not by reading

- `:joryio` and `:joryio-ui` · `compileReleaseKotlin` ✓
 - `:joryio_react-native-sdk:compileReleaseKotlin` ✓ — precisely what broke on the previous four pulls
 - `xcodebuild -scheme Joryio -destination 'generic/platform=iOS'` · **BUILD SUCCEEDED** ✓
 - `tsc` clean against the new types · **2,562 tests passing**
- `swift build` on its own fails on UIKit because it targets macOS. That is an environment limit, not a defect — it fails identically against the untouched upstream sources.

Not done

- **No build was produced and nothing was submitted to the stores** — the change sits in the working tree and ships with the next build
- No application code changed: none of the new capabilities are in use yet
